# ABSTRACT

↙ This report contains test results on ANB-3066 propellant manufactured by Aerojet Solid Propulsion Company and Thiokol Corporation. Statistical comparison of all types was made on the basis of similar ages.

Propellants were analyzed with respect to the type of polymer used in the manufacturing process and by carton type.

Regressions are given for very low rate tensile, high rate biaxial tensile under pressure, stress relaxation and case liner bonds.

The test results indicate dissimilarity between Minuteman II, Stage II and Minuteman III, Stage III propellant as described by the linear regression analysis. ↙

## GLOSSARY OF ABBREVIATIONS AND TERMS

Aging Trend	A change in properties of performance resulting from aging of material or component
ANA	Aerojet Propellant, Stage III (ANB 3066 Formulation)
ANT	Thiokol Propellant, Stage III (ANB 3066 Formulation)
ANB	Aerojet Propellant, Stage II (ANB 3066 Formulation)
ASPC	Aerojet Solid Propulsion Company
CSA	Cross Sectional Area
DB	Dogbone
Degradation	Gradual deterioration of properties or performance
E	Modulus (psi), defined as the slope of the line drawn tangent to the initial linear portion of the curve
EB	End Bonded
EGL	Effective Gage Length
$\epsilon_m$	Strain at Maximum Stress (in/in)
$\epsilon_r$	Strain at Rupture (in/in)
"F" ratio	The ratio of the variance accounted for by the regression function to the random unexplained variance. The regression function having the most significant "F" ratio is used for plotting data. The ratio is also used in detecting significant changes in random variation between succeeding time points.
JANNAF	Joint Army, Navy, NASA, Air Force Committee
MAGCP	Propellant Laboratory at OOAMA
OOALC	Ogden Air Logistics Command
Post Curing	Period up to 12-16 months after manufacture

# GLOSSARY OF ABBREVIATIONS AND TERMS (CONT.)

Regression	The general form of the regression equation is $Y = a + bx$
Regression Line	Line representing mean test values with respect to time
$S_b$	Standard error of estimate of the regression coefficient
$S_e$ or $S_{Y.X}$	Standard deviation of the data about the regression line
$S_m$	Maximum Stress (psi)
$S_r$	Stress at Rupture (psi)
Standard Deviation ( $S_y$ )	Square root of variance
Strain Rate	Crosshead speed divided by the EGL
Thiokol	Thiokol/Wasatch Division
"t" Test	A statistical test used to detect significant differences between a measured parameter and an expected value of the parameter (determines if regression slope differs from zero at the 95% confidence level)
Variance	The sum of squares of deviations of the test results from the mean of the series after division by one less than the total number of test results
3 Sigma Band	The area between the upper and lower 3 sigma limit. It can be expected that 99.73% of the inventory represented by the test samples would fall within this range assuming that the population is normally distributed.
90-90 Band	It can be stated with 90% confidence that 90% of the inventory represented by the test samples would fall within this range assuming that the population is normally distributed.

## SECTION I INTRODUCTION

### A. PURPOSE:

The purpose of testing ANB-3066 propellant, used in Minuteman II Stage II and Minuteman III Stage II and Stage III, is to monitor and evaluate aging effects on this propellant which will contribute to the operational motor serviceability prediction. Testing was performed according to General Test Directive GTD-2C, Amendment 1, and MMWRM Project M82937C and M82938C.

### B. BACKGROUND:

Service life testing of ANB-3066 carton propellant from Aerojet production began at Ogden ALC in 1966. When production for Minuteman III Stage II was transferred to Thiokol, the propellant samples from both Aerojet and Thiokol were tested. As lined cartons were produced these were tested, adding propellant liner bond specimens to the program. This report contains data from all these sources for propellant aged 13 to 137 months.

Failure criteria for ANB-3066 propellant which were developed from structural stress analysis are reiterated in Aerojet Report 0162-06SAAS-17. Inner bore hoop strain failure is the predicted failure mode. These criteria are shown in Table 1-1.

## SECTION II TEST PROGRAM

Cartons representing raw material combinations were subjected to a random selection process designed to test all material lots within a two year-four test periods interval. When propellant cartons have been aged one year, they are added to the test program.

Propellant cartons are identified by source of manufacture. Stage II and III propellant manufactured by Aerojet Solid Propulsion Company is identified as ANB and ANA respectively. Thiokol Company Stage III propellant is identified as ANT. All regressions used this nomenclature and the additional information as to the type of carton, lined or unlined. Symbols are used on multiple regressions to separate types. There were two suppliers for polymers for Stage II propellant, "G" polymer manufactured by General Tire and Rubber and "P" polymer from Phillips. Until recently, the extremely large variations in data from certain lots had been combined with cartons having negligible standard deviations. In this report the two polymer types have been treated statistically.

Stage II ANB-3066 propellant has been tested for more than 10 years, but in this report only propellant up to 72 months has been used in covariance analysis to coincide with the age span of Stage III propellant. Lined and unlined cartons of ANB have been combined in regression analysis for comparison purposes and cover the time span from 13 through 137 months.

The physical-mechanical tests which relate directly to stress analysis are limited. Very low rate tensile test data is related to storage

conditions, and high rate rails tested under pressure relate to ignition. Stress relaxation modulus also relates to storage conditions. Thermal coefficient of linear expansion reflects some of the thermal stresses to which the motor is exposed.

Low rate uniaxial tensile tests and hardness are routine tests for all propellant. These data have been subjected to statistical analyses in this report. Poisson's ratio and cohesive tear energy tests have been applied to only a portion of the cartons. Data from these tests will be more rigorously analyzed the next reporting period.

SECTION III  
STATISTICAL SUMMARY AND CONCLUSIONS

Data analyses of all propellant tested by MANCP having the ANB 3066 formulation are contained in this report. ANB 3066 propellant is divided into three groups, each group pertaining to a specific rocket motor application. These propellant groups are further classified with regards to the manufacturer of the polymer contained in the propellant. The two manufacturers of ANB 3066 polymer are General Tire and Rubber ('G' type) and Phillips ('P' type). The three propellant groups are designated in this report as follows:

<u>Code</u>	<u>Polymer Type</u>	<u>Manufacturer and System Application</u>
ANA	G	Aerojet: MINUTEMAN III, Stage III
ANB	G and P	Aerojet: MINUTEMAN II, Stage II
ANT	P	Thiokol: MINUTEMAN III, Stage III

Propellant specimens for the ANA group were taken from unlined cartons and contains only "G" type polymer. Specimens for the ANB and ANT groups were taken from unlined cartons and also from cartons having a simulated case liner along one surface of the carton. Propellant from the ANB group contains both "G" and "P" type polymers. ANT propellant contains only "P" type polymer. Each propellant group is further sub-divided into propellant lots.

Test data were analyzed to test for similarities between propellant lots within a given propellant group, as well as polymer type and carton type. The following comparisons, directed by the project engineer, were performed in support of service life estimation:

1. Compare lined and unlined cartons of Minuteman III Stage III propellant manufactured by Thiokol. (ANT lined vs ANT unlined).
2. Compare Aerojet Stage II lined cartons (ANB propellant group) with Thiokol Stage III lined cartons. (ANB lined vs ANT lined).
3. Perform lot-to-lot comparisons for unlined cartons with 'G' type polymer from the ANA and ANB propellant groups (ANA 'G' vs ANB 'G').
4. Perform lot-to-lot comparisons for lined cartons with 'P' type polymer from the ANB and ANT propellant groups (ANB 'P' vs ANT 'P').
5. Compare unlined cartons with 'G' type polymer and unlined cartons with 'P' type polymer from the ANB propellant group. (ANB 'G' unlined vs ANB 'P' unlined).
6. Compare lined cartons with 'G' type polymer and lined cartons with 'P' type polymer from the ANB propellant group. (ANB 'G' lined vs ANB 'P' lined).
7. Perform lot-to-lot comparisons for each propellant group with a given polymer (ANA 'G' lots; ANB 'G' lots; ANB 'P' lots; etc.,)

Propellant age is considered a possible source of bias in laboratory test data. That is, part of the observed differences in a given test response might be ascribed to propellant age. Because of the possible age effect it is necessary to provide a means of analysis where the bias, or age effect, could be removed allowing an unbiased evaluation of the true parameter response.

Analysis of covariance was chosen as the method to determine the effect or "significance" of propellant age on the test response. The general linear regression model,  $Y = a + b(X_{ij})$ , is modified for the analysis of covariance by introducing a "correction term" into the model to adjust the data for the average effect of the variable  $X_{ij}$ . Propellant age was assigned to the variable  $X_{ij}$  in this report.

Similarity among carton types and among propellant groups was determined by comparing regression lines for each of the data sets. The purpose was to examine whether the linear regressions of the test response on propellant age could be regarded as the same. It is possible for the regressions to differ in slope, intercept or residual variance. Differences due to slope could indicate dissimilar aging characteristics among groups while differences due to intercept could indicate bias among the data sets. When the regression lines were statistically similar (slopes and intercepts were not significantly different) the data sets were accepted as being equal and were combined to provide an expanded data base. A "total" or composite regression line was then used to estimate the aging trend for the combined data.

ANB 3066 propellant exhibits incomplete curing and inconsistent test results if aged less than 13 months. All data aged less than 12 months was excluded from analysis in this report.

In those cases where test data from various carton types or propellant groups could be combined, plots of the combined data and regression lines are provided. Carton types or propellant groups are differentiated on these plots with different plotting symbols. These are shown in the applicable test sections. In addition to the combined regression plots, plots of individual group regression lines have been provided for each test parameter where the regression slope is statistically significant.

Test data for JANNAF dogbones tested at 2.0 in/min crosshead speed and short 3/4" dogbones tested under 600 psi  $N_2$  at 1750 in/min crosshead speed were not subjected to analysis of covariance. Data from these tests were compared by plotting regression lines for each group on the same graph to

allow visual comparison of regression lines. In addition to these graphs, Tables 10-1 thru 10-6 show regression statistics for each data group.

The results of the analyses performed are summarized as follows:

1. ANT lined and unlined cartons are significantly different for all observed test parameters.
2. ANB and ANT lined cartons are significantly different for all observed test parameters.
3. ANA and ANB unlined cartons with the 'G' type polymer are significantly different.
4. ANB and ANT lined cartons with 'P' polymer have significantly different regression slopes.
5. ANB and ANT unlined cartons with 'G' polymer, and unlined cartons with 'P' polymer show no similarities for observed test parameters.
6. ANB 'G' lined cartons and ANB 'P' lined cartons are significantly different for all observed parameters.
7. Significant lot-to-lot differences due either to regression slope or intercept are indicated for all propellant groups and tests with the following exception:

Propellant lots are similar for the ANB 'P' propellant from unlined cartons on the tensile test at 0.0002 in/min crosshead speed and stress relaxation modulus at 10 seconds relaxation time. The results are shown in Table 3-1.

A comparison of the standard deviations for three major tests is shown in Table 3-2. The standard deviation is very high for ANB "P" propellant from unlined cartons. ANT "P" unlined cartons show a similar high standard deviation, which is reflected in the combinations of ANB "G" and "P" and ANB and ANT "P" unlined cartons.

A less consistent pattern of standard deviation is shown in the high rate triaxial test. However, the combination of ANB "G" and "P" unlined cartons shows very high standard deviation.

Stress relaxation modulus also shows greater standard deviation for unlined cartons of "P" polymer which was used by Aerojet.

In summary, it may be concluded that the great variability in trend lines shown in previous reports can be related to the fact that two polymer sources were used in the manufacture of ANB-3066 propellant, as well as two manufacturers. The greater variability of "P" polymer is apparent from Table 3-2. Since there are also lot-to-lot differences to reconcile, it is not unreasonable to find that the standard deviation is affected by the lots tested.

#### SECTION IV

##### VERY LOW RATE TENSILE

This test uses a 1/2 inch thick (1.27cm) JANNAF dogbone. The specimens are tested at a crosshead speed of  $2 \times 10^{-4}$  in/min ( $8.5 \times 10^{-2}$  cm/sec) 77°F (250°C) and ambient RH. Very low rate tensile testing is related to strain capability for storage at 60°F.

Lined cartons show a statistically significant decrease in strain at rupture. This holds true for both polymer types and for combinations. (Figures 4-8, 4-14, 4-20, 4-29 and 4-35.) Maximum stress and modulus are statistically increased. (Figures 4-7, 4-13, 4-19, 4-28, 4-34 and 4-9; 4-15, 4-21, 4-30 and 4-36).

Maximum stress shows a statistically significant increase except for the combination ANA and ANBG unlined cartons, where the increase is not significant. (Figures 4-1, 4-4, 4-10, 4-16, 4-25, 4-31 and 4-32).

As previously noted, strain at rupture decreases significantly in lined cartons. Unlined cartons show a statistically significant increase except for ANA where the increase is not significant. (Figures 4-5, 4-11, 4-17, 4-23, 4-26, 4-32 and 4-2).

Modulus is the least consistent of the parameters since unlined cartons show both increases and decreases which may be significant or not significant.

Unlined cartons of "P" polymer have a lower strain at rupture than "G" polymer and show a greater standard deviation. Unlined cartons have a lower strain at rupture than lined cartons regardless of polymer type.

In summary, lined cartons show greater consistency than unlined cartons with lower standard deviations.

ANB 3066 PROPLNT (ANT 6 ANR LIND, P POLYMER) TENSILE MODULUS, .0002 IN/MIN

SECTION V  
HIGH RATE TRIAXIAL

This test utilizes a specimen  $3/4$  inch (1.9 cm) GL rail by 5 inches (12.7 cm) long. The specimens are tested on the MTS at a crosshead speed of 1750 in/min (74.08 cm/sec) with 600 psi (42.18 kg/sq cm). Strain rate is 1000 in/in/sec. These conditions simulate that of the motor at ignition.

This test does not show the significant changes which are characteristic in the very low rate tensile test. No type or combination of types has significant change in all parameters. ANT propellant shows a significant increase in maximum stress and a significant decrease in strain at rupture. Modulus shows a non-significant decrease (see Table 5-1).

The most consistent statistical feature of the test is the lower standard deviation of lined cartons compared to unlined cartons. This characteristic is most noticeable in the standard deviation of modulus which, in many cases, is less than half that of unlined cartons. Since determination of a consistent modulus has been a problem in high rate testing, the much reduced deviation in lined cartons seems all the more remarkable.

AGE 3050 PROPYLENE (ANT 8 AND LINO. P POLYMER) TENSILE MOD, 1750 IN/MIN 600 PSI

## SECTION VI

### STRESS RELAXATION

An end-bonded 1/2" x 1/2" x 4" bar (1.27 x 1.27 x 10.16 cm) is tested on the stress relaxometer. Load is applied at 2 in/min (.085 cm/sec). Timing begins when load is applied. Specimens are strained at 1%.

The use of 1% strain over the range of temperatures was not introduced into the test program until Phase 3 of Minuteman III testing and Phase B Series 2 for Minuteman II. Master curves (Figures 6-1 thru 6-7) show that the temperature shift is not linear and deviation from linearity is most marked at elevated temperatures. There is very little consistency in the super-positioning. For example, ANA (G Propellant) unlined cartons, corresponds well with ANT (P Propellant) lined cartons. This agreement is better than between lined and unlined cartons of the same type. There is better agreement at elevated temperatures than at cold temperatures, where the differences are noticeable with all systems.

In general, stress relaxation modulus shows a significant increase. The exception is ANB 'G' which shows a significant decrease. (Figures 6-10 and 6-11) which holds when combined with ANA (Figures 6-22 and 6-23).

When gradient stress relaxation is run there is a definite bias between ANB and ANT propellant with ANT (P polymer) showing a higher modulus. The minima exhibited by both ANT and ANB occurs at 2.2 inches from the liner (Figure 6-32).

## SECTION VII

### THERMAL COEFFICIENT OF LINEAR EXPANSION

Thermal coefficient of linear expansion (TCLE) is run on the DuPont 990 TMA using an expansion probe. The specimen used is a wafer approximately .200" (.508 cm) thick by .33" diameter (.84 cm). The specimen is cooled with liquid nitrogen to  $-110^{\circ}\text{C}$  then heated at  $5^{\circ}\text{C}/\text{min}$  to  $40^{\circ}\text{C}$  and the glass point ( $T_g$ ), TCLE below  $T_g$  and above  $T_g$  are determined.

In the past, TCLE above  $T_g$  has been obtained from a line extrapolated from  $-110^{\circ}\text{C}$  to plus  $40^{\circ}\text{C}$ . This has resulted in high values of TCLE. Thermal expansion of propellant is not linear and varies considerably when determined in  $20^{\circ}$  increments from  $T_g$  to  $40^{\circ}\text{C}$ . The average value from incremental values is now being used and previous data is being revised to reflect this change as well as to enter data from recent testing.

Based on available data, unlined cartons show a significant increase in TCLE with a decrease in glass point. Regression analysis will be given in the next report.

## SECTION VIII

### CASE LINER BONDS

Cartons of propellant were lined with SD-851-2 liner/V45 rubber. In the preparation of the cartons, liner sometimes penetrates the propellant to a depth of 0.5 inches. Irregularities are most apparent on outer surfaces, and corners may be particularly affected by curvature of the insulation.

Liner color varies from a pale buff to a deep pink which apparently develops from the anti-oxidant used. In general, the pink liner tends to be sticky and strings out in tensile testing.

Aerojet did a study of 44 manufacturing variables to determine those which had a significant effect on liner bond strength. According to their report (MVS-1, June 76) several factors had a statistically significant effect on bond strength. Initial high bond strength and low insulation moisture content usually mean a longer time to degradation of the liner bond.

Constant load tensile and constant load shear data from several test periods have been summarized in Table 8-1. Tensile stress to cause failure in 100 minutes is slightly less than in the previous report, but above the 23.1 psi alert limit for storage for Stage II. Shear stress to cause failure at 100 minutes is slightly greater than in the previous report and is above the alert limit of 15.4 psi. Regressions are shown in Figures 8-1 through 8-4.

Mini-DPT data are given in Tables 8-2 and 8-3. These data have not been subjected to regression analysis. In many of the specimens two maxima occur and maximum stress may be early or late in the test. There does not appear to be any correlation between maximum stress, time to failure and type of failure.

Moisture in insulation has shown much variability and results have not been subjected to statistical analysis. This is also true of liner-swell ratio.

TABLE 8-1

## SECTION IX

### HARDNESS

A Shore A Durometer is used to take initial and 10 second readings on dogbone ends.

Unlined cartons of ANB(G) propellant show a significant decrease in hardness, but lined cartons show a significant increase. ANB(P) propellant shows a significant increase in hardness for both unlined and lined cartons. ANT(P) lined cartons do not show a significant change while there is a significant increase for unlined cartons. ANA(G) cartons show a significant increase. Usually the intercept is higher for unlined cartons than lined cartons and the standard deviation ( $S_y$ ) is greater.

A small scale comparison of hardness data was made between G and P polymer blocks, taking the first reading on the uncut surface of the carton. These data are shown in Tables 9-1 and 9-2. Each value is an average of five readings, using both sides of a dogbone. The cutting plans for lined and unlined cartons differ (see drawings A-1 and A-2). (Drawing A-3 shows the cutting plan for Thiokol's unlined cartons). Therefore, a true gradient exists only in the unlined cartons. The data do not reflect a trend, and in some cases, surface hardness is less than for the interior of the carton. No categorical statements can be made from this data, since there are differences between the two types of polymer and between lined and unlined cartons.

SECTION X  
OTHER TENSILE TESTS

A. LOW RATE UNIAXIAL TESTS:

Low rate uniaxial tests are routinely run on ANB-3066 propellant. Standard JANNAF specimens are tested on the Instron at 2 in/min (.0847 cm/sec) at 77°F (25°C).

Three parameters: maximum stress, strain at rupture and modulus were chosen for multiple regressions. There are two plots for each parameter; one comparing ASPC 'G' polymer with Thiokol 'P' polymer and the other comparing 'P' propellants with ANA 'G' as a base line (Figures 10-1 thru 10-6). Regression information is given in Tables 10-1 thru 10-3.

Except for ANB 'G' lined cartons and ANB 'P' unlined cartons there is a significant change in maximum stress. These two types do not show a significant change in strain at rupture or in modulus.

B. MODIFIED DOGBONES:

Modified dogbones with 3/4" GL are tested under 600 psi nitrogen pressure (42.18 kg/cm<sup>2</sup>) at 1750 in/min (74.08 cm/sec).

A comparison similar to that for low rate tensile was made on the data (Figures 10-7 thru 10-12 and Tables 10-4 thru 10-6). ANA 'G' unlined cartons and ANB 'P' lined and unlined cartons show significant changes in all three parameters. Other types showed a significant increase in modulus.

20. ABSTRACT (Continue on reverse side if necessary and identify by block number)  This report contains test results on ANB-3066 propellant manufactured by Aerojet Solid Propulsion Company and Thiokol Corporation. Statistical comparison of all types was made on the basis of similar ages. Propellants were analyzed with respect to the type of polymer used in the manufacturing process and by carton type. Regressions are given for very low rate tensile, high rate biaxial tensile under pressure, stress relaxation and case liner bonds. (over)		

407387

yB

The test results indicate dissimilarity between Minuteman II, Stage II and Minuteman III, Stage III propellant as described by the linear regression analysis.
